Started Monday, 23 December 2024, 5:33 PM

Alice and Bob are playing a game called "Stone Game". Stone game is a two-

player game. Let N be the total number of stones. In each turn, a player can

remove either one stone or four stones. The player who picks the last stone,

make the first move. Your task is to find out whether Alice can win, if both play

First line starts with T, which is the number of test cases. Each test case will

wins. They follow the "Ladies First" norm. Hence Alice is always the one to

Question **3** Correct Marked out of 7.00 ▼ Flag question

10 4 **Sample Input 2:** 5 3

Add the holes count for each digit, 1, 2, 8, 8. Return 0 + 0 + 2 + 2 = 4. Answer: (penalty regime: 0 %) #include <stdio.h> int main(){ 3 int num,sum=0,rem; scanf("%d",&num); while (num>0){ rem=num%10; else if (rem==8) num=num/10; printf("%d",sum); return 0; Input Expected Got 2 630 2 4 1288 Passed all tests! <

sum=sum+1; sum=sum+2; **✓ /**

if (rem==0||rem==4||rem==6||rem==9) The problem solvers have found a new Island for coding and named it as Philaland. These smart people were given a task to make a purchase of items at the Island easier by distributing various coins with different values. Manish has

come up with a solution that if we make coins category starting from \$1 till the maximum price of the item present on Island, then we can purchase any item easily. He added the following example to prove his point. Let's suppose the maximum price of an item is 5\$ then we can make coins of {\$1, \$2, \$3, \$4, \$5}to purchase any item ranging from \$1 till \$5. Now Manisha, being a keen observer suggested that we could actually minimize the number of coins required and gave following distribution {\$1, \$2, \$3}. According to him any item can be purchased one time ranging from \$1 to \$5. Everyone was impressed with both of them. Your task is to help Manisha come up with a minimum number of denominations for any arbitrary max price

Input Format Contains an integer N denoting the maximum price of the item present on **Output Format** Print a single line denoting the minimum number of denominations of coins **Constraints** 1<=T<=100 1<=N<=5000

Refer the sample output for formatting **Sample Input 1: Sample Output 1:**

Sample Output 2: Explanation: For test case 1, N=10.

But as per Manisha only {\$1, \$2, \$3, \$4} coins are enough to purchase any item

ranging from \$1 to \$10. Hence minimum is 4. Likewise denominations could

According to Manish {\$1, \$2, \$3,... \$10} must be distributed.

According to Manish {\$1, \$2, \$3, \$4, \$5} must be distributed.

also be {\$1, \$2, \$3, \$5}. Hence answer is still 4.

For test case 2, N=5.

Question **2** Correct Marked out of 5.00 ▼ Flag question

Question **3** Correct Marked out of 7.00 Flag question

2 1 2

Explanation 1 time. Sample Case 2 Sample Input 2 3 3 **Sample Output 2**

5 **Explanation 2** 2 + 3 = 5, is the best case for maximum nutrients. **Answer:** (penalty regime: 0 %)

11 12 13 14 15 16 17 18 Input Expected Got 89 25 Passed all tests! < A nutritionist is labeling all the best power foods in the market. Every food item arranged in a single line, will have a value beginning from 1 and increasing by 1 for each, until all items have a value associated with them. An item's value is the same as the number of macronutrients it has. For example, food item with number.

value 1 has 1 macronutrient, food item with value 2 has 2 macronutrients, and incrementing in this fashion. The nutritionist has to recommend the best combination to patients, i.e. maximum total of macronutrients. However, the nutritionist must avoid prescribing a particular sum of macronutrients (an 'unhealthy' number), and this sum is known. The nutritionist chooses food items in the increasing order of their value. Compute the highest total of macronutrients that can be prescribed to a patient, without the sum matching the given 'unhealthy' Here's an illustration: Given 4 food items (hence value: 1,2,3 and 4), and the unhealthy sum being 6 macronutrients, on choosing items 1, 2, 3 -> the sum is 6, which matches the 'unhealthy' sum. Hence, one of the three needs to be skipped. Thus, the best combination is from among: 2 + 3 + 4 = 91 + 3 + 4 = 81 + 2 + 4 = 7Since 2 + 3 + 4 = 9, allows for maximum number of macronutrients, 9 is the right answer. Complete the code in the editor below. It must return an integer that represents the maximum total of macronutrients, modulo $1000000007 (10^9 + 7)$. It has the following: **Constraints** $1 \le n \le 2 \times 10^9$ $\cdot \qquad 1 \le k \le 4 \times 10^{15}$

n: an integer that denotes the number of food items *k*: an integer that denotes the unhealthy number Input Format For Custom Testing The first line contains an integer, *n*, that denotes the number of food items. The second line contains an integer, k, that denotes the unhealthy number. Sample Input 0 **Sample Output 0**

2

2

3

Explanation 0 The following sequence of n = 2 food items: Item 1 has 1 macronutrients. 1 + 2 = 3; observe that this is the max total, and having avoided having exactly k = 2 macronutrients. Sample Input 1 **Sample Output 1**

Sample Input For Custom Testing

Cannot use item 1 because k = 1 and $sum \equiv k$ has to be avoided at any

Hence, max total is achieved by sum = 0 + 2 = 2.

#include <stdio.h>

return 0;
